# The genetics of complex traits: historical context and current challenges

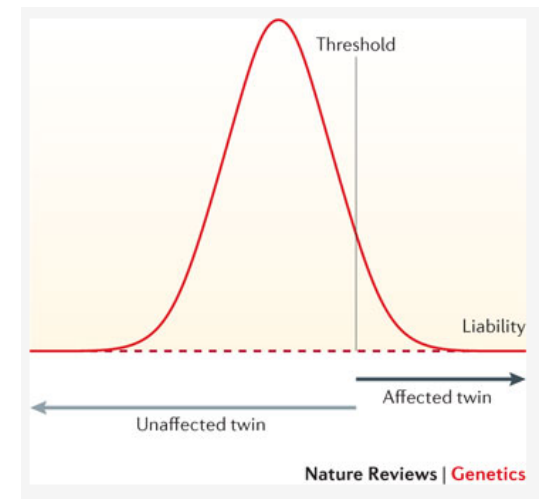

Nick Martin  
Queensland Institute  
of Medical Research  
Brisbane

Boulder workshop  
March 4, 2019

# Human variation: Height

# Human variation: IQ

# Genetic Epidemiology: Stages of Genetic Mapping

- Are there genes influencing this trait?
  - Genetic epidemiological (twin / family) studies OR heritability based on measured genetic variants
- Where are those genes?
  - Linkage analysis
- What are those genes?
  - Association analysis (meta-analysis / pathway)
- How do they work beyond the sequence?
  - Epigenetics, transcriptomics, proteomics
- What can we do with them ?
  - Translational medicine

# Total mole count for MZ and DZ twins

MZ twins - 153 pairs,  $r = 0.94$

DZ twins - 199 pairs,  $r = 0.60$

# 4 Stages of Genetic Mapping

- Are there genes influencing this trait?
  - Genetic epidemiological studies
- Where are those genes?
  - Linkage analysis
- What are those genes?
  - Association analysis
- What can we do with them ?
  - Translational medicine

Thomas Hunt Morgan – discoverer of linkage

# Linkage analysis

x

1/4

1/4

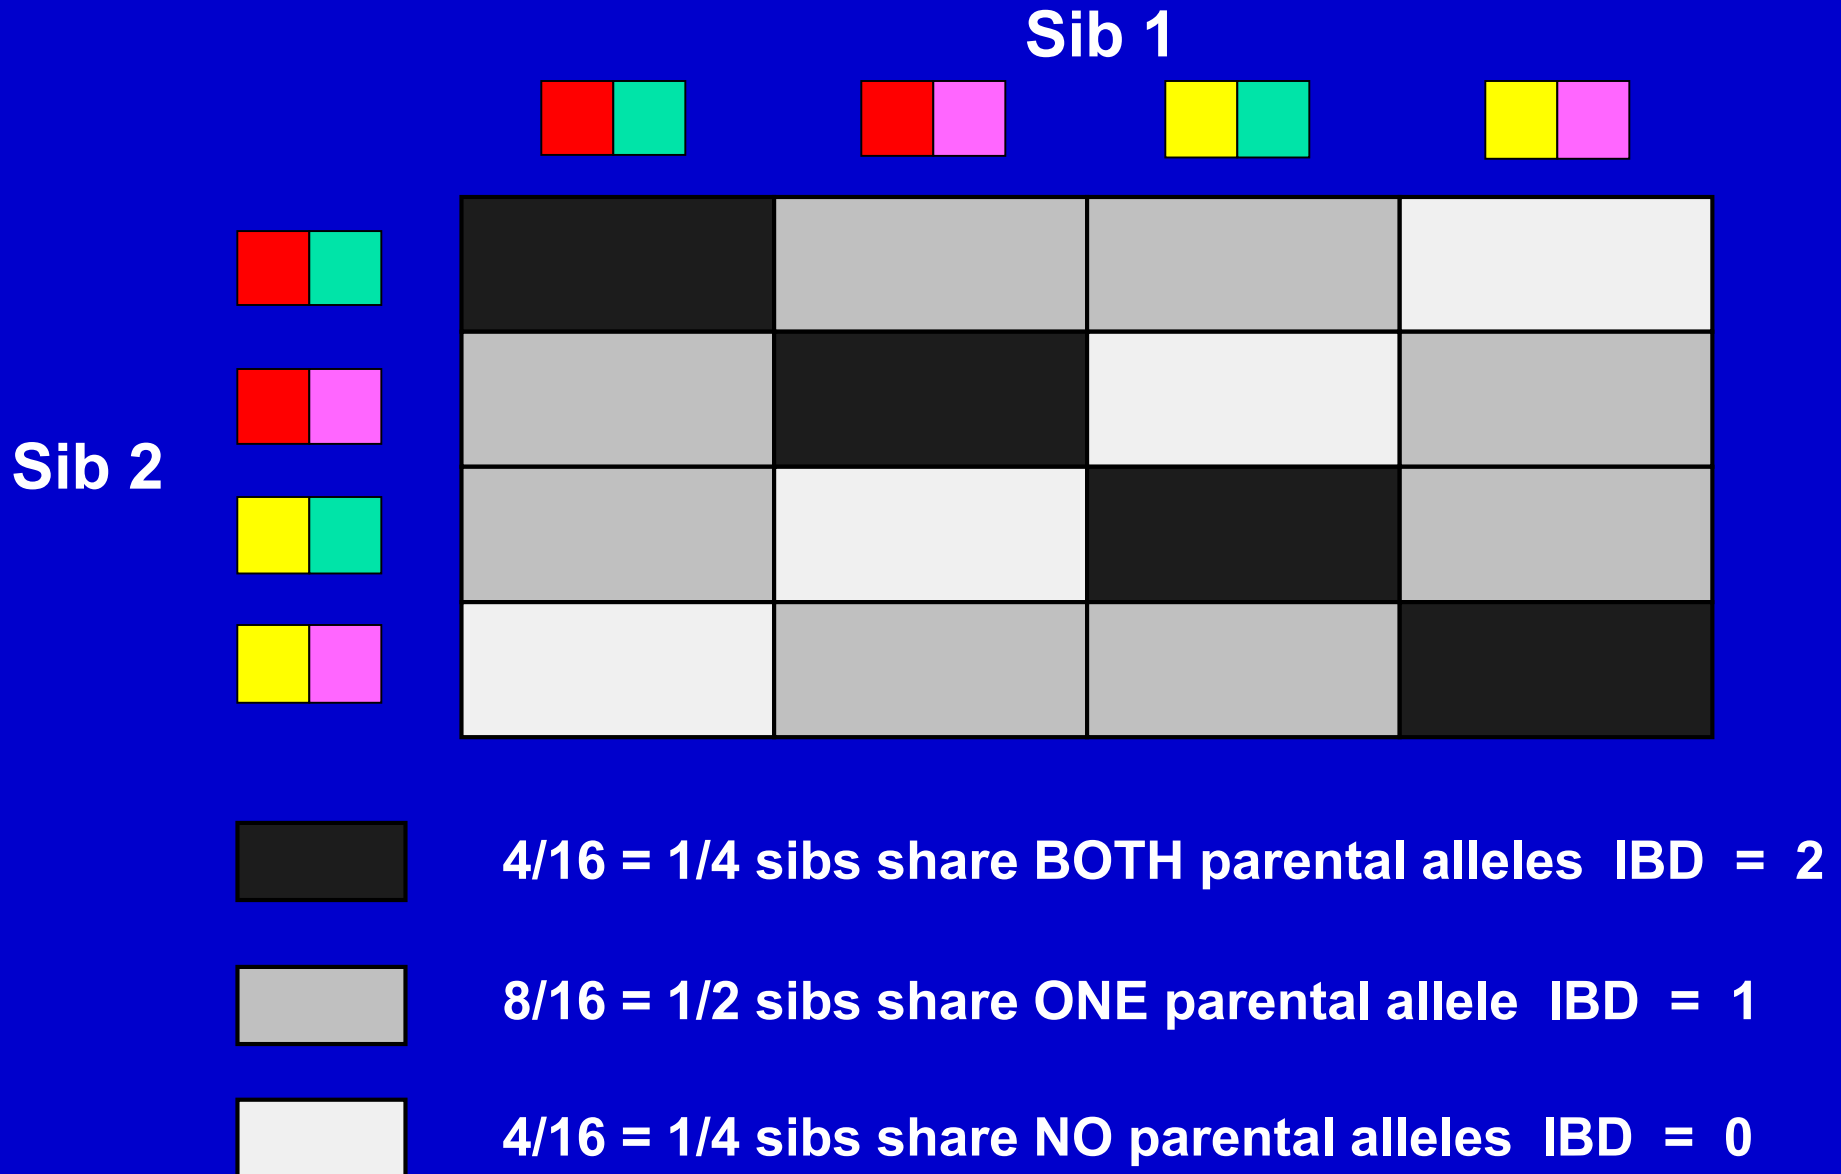

1/4

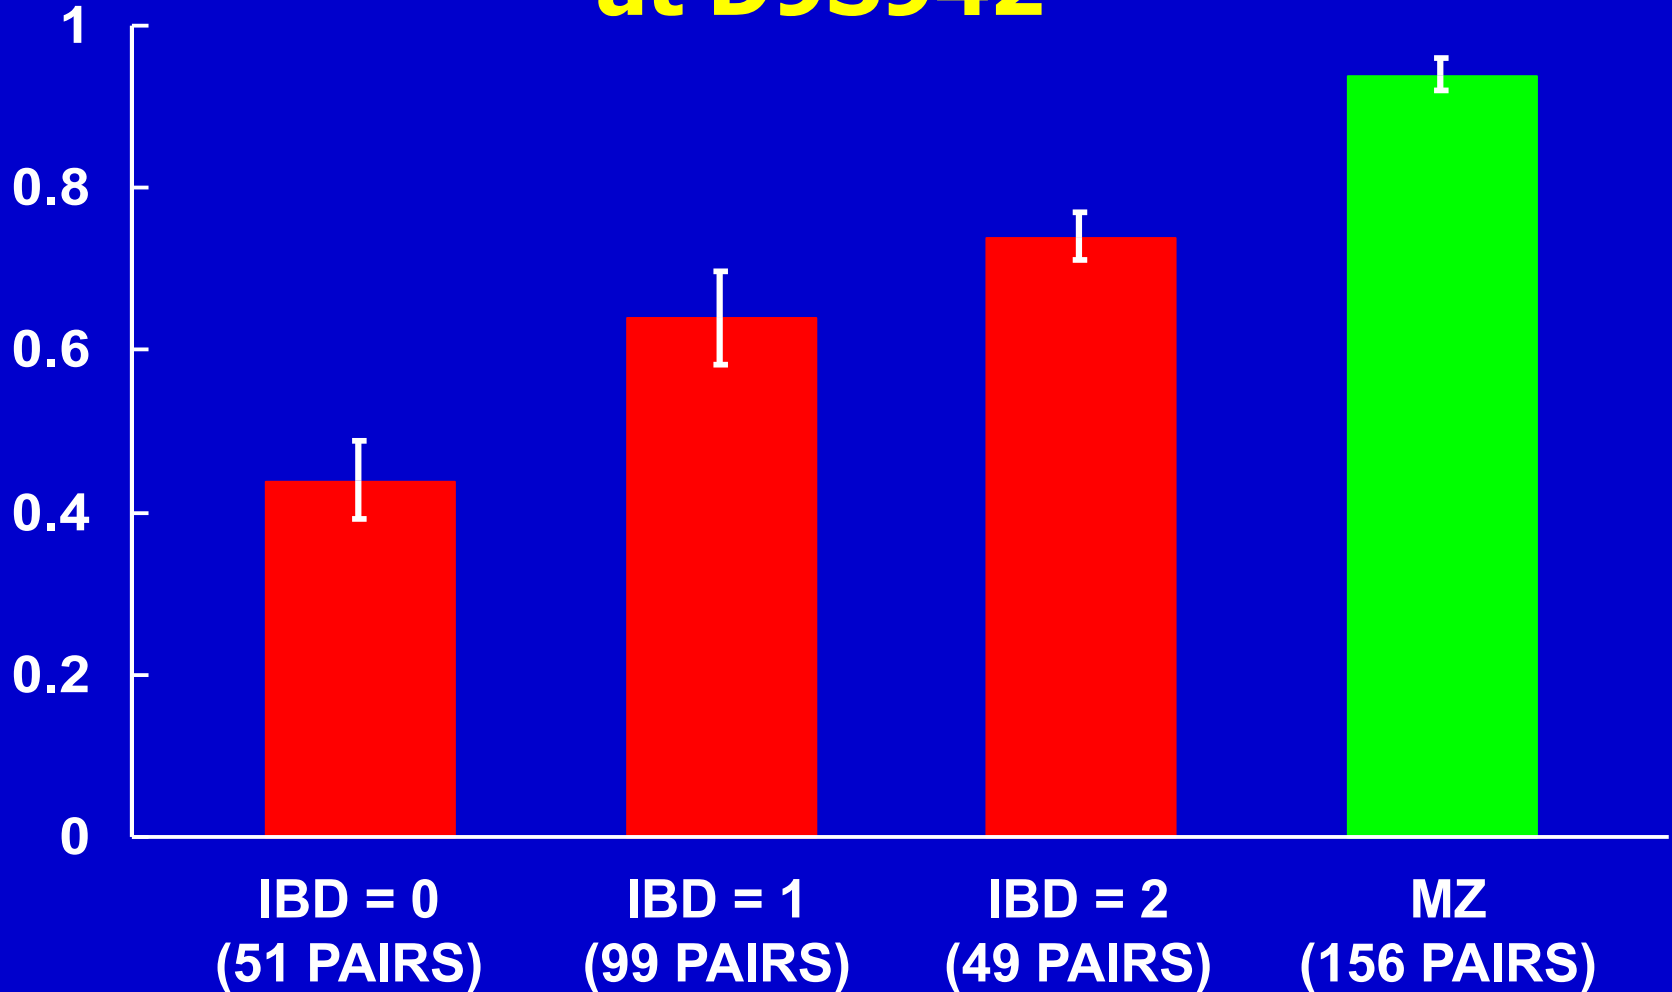

1/4

# IDENTITY BY DESCENT

# Total nevus count correlations by IBD class at D9S942

Heterogeneous ( $\chi^2_2=12.58, p=0.002$ )

# Human OCA2 and eye colour

QTL for Eye Colour

Chromosome 15

- Linkage analysis is badly underpowered for complex traits with small gene effect sizes
- So we need a much more sensitive way to find the genes

# Complex disorders account for most health burden

- Examples
  - Ischaemic heart disease (30-50%, F-M)
  - Breast cancer (12%, F)
  - Colorectal cancer (5%)
  - Recurrent major depression (10%)
  - ADHD (5%)
  - Bipolar (2%)
  - Schizophrenia (1%)
  - Non-insulin dependent diabetes (5%)
  - Asthma (10%)
  - Essential hypertension (10-25%)
  - etc.....

# Basic principle of genetic association studies

**Genetic Variant 1**

**Genetic Variant 2**

**Affected**

**Affected**

**Unaffected**

**Unaffected**

# Association analysis

looks for correlation between specific alleles and phenotype  
(trait value, disease risk)

## Single Nucleotide Polymorphisms (SNPs)

# High density SNP arrays – up to 1 million SNPs

# Genome-Wide Association Studies

**500,000 – 5,000,000 SNPs**  
**Human Genome -  $3,1 \times 10^9$  Base Pairs**

# Linkage disequilibrium

# Linkage disequilibrium

# Indirect association

this SNP will be associated with disease

# Linkage disequilibrium blocks

# Genetic Case Control Study

---

Allele **G** is 'associated' with disease

# Allele-based tests (case-control)

- Each individual contributes two counts to 2x2 table.
- Test of association

$$X^2 = \sum_{i=0,1} \sum_{j=A,U} \frac{(n_{ij} - E[n_{ij}])^2}{E[n_{ij}]}$$

where

$$E[n_{ij}] = \frac{n_{i\cdot} \cdot n_{\cdot j}}{n_{\cdot\cdot}}$$

- $X^2$  has  $\chi^2$  distribution with 1 degrees of freedom under null hypothesis.

	Cases	Controls	Total
G	$n_{1A}$	$n_{1U}$	$n_{1\cdot}$
T	$n_{0A}$	$n_{0U}$	$n_{0\cdot}$
Total	$n_{\cdot A}$	$n_{\cdot U}$	$n_{\cdot\cdot}$

# Simple Regression Model of Association (continuous trait)

$$Y_i = \alpha + \beta X_i + e_i$$

where

$Y_i =$  trait value for individual  $i$

$X_i =$  number of 'A' alleles an individual has

Association test is whether  $\beta > 0$

# Genome-wide association study in alopecia areata implicates both innate and adaptive immunity

Lynn Petukhova<sup>1</sup>, Madeleine Duvic<sup>2</sup>, Maria Hordinsky<sup>3</sup>, David Norris<sup>4</sup>, Vera Price<sup>5</sup>, Yutaka Shimomura<sup>1</sup>, Hyunmi Kim<sup>1</sup>, Pallavi Singh<sup>1</sup>, Annette Lee<sup>6</sup>, Wei V. 	<i>HLA-DQA2</i>	Antigen presentation	$1.38 \times 10^{-35}$	5.43	T1D, RA
	<i>HLA-DQB2</i>	Antigen presentation	$1.73 \times 10^{-13}$	1.60	RA

Each of the eight regions implicated in our study contains multiple significant SNPs, which are detailed in Supplementary Tables 1 and 2. Here we display candidate genes within the implicated regions, and include the *P* value of the most significant SNP, and the odds ratio for the SNP with the largest effect estimate. Diseases are listed for which a GWAS or previous candidate gene study identified the same region (<http://www.genome.gov/gwastudies>, <http://www.cdc.gov/genomics/hugenet>): Crohn's disease (CD), celiac disease (CeD), Graves disease (GD), generalized vitiligo (GV), multiple sclerosis (MS), psoriasis (PS), rheumatoid arthritis (RA), system lupus erythematosus (SLE), type 1 diabetes (T1D), and ulcerative colitis (UC).

# Discovery of the first genome-wide significant risk loci for attention deficit/hyperactivity disorder

Ditte Demontis , Raymond Walters .... Sarah Medland .... Benjamin Neale

20,183 ADHD cases  
35,191 controls  
12 independent GWS loci,

we developed a novel model to **meta-analyze the GWAS of the continuous measure of ADHD with the clinical diagnosis** in the ADHD GWAS. In brief, we perform a z-score based meta-analysis using a weighting scheme derived from the SNP heritability and effective sample size for each phenotype that fully accounts for the differences in measurement scale

**How to combine binary and continuous measures in GWAS**

# GWAS publications since 2005

As of July 2017

- 3,055 publications
- 44,619 variant-trait associations

---

# Functional interpretation GWAS results

Find the right target gene

REVIEW

## Approaches for establishing the function of regulatory genetic variants involved in disease

Julian Charles Knight

A local *cis*-acting variant   
in a regulatory element   
affects allele-specific  
transcription factor  
binding affinity and is  
associated with  
differential expression of  
gene A (see chart)

**REVIEW**

## Approaches for establishing the function of regulatory genetic variants involved in disease

Julian Charles Knight

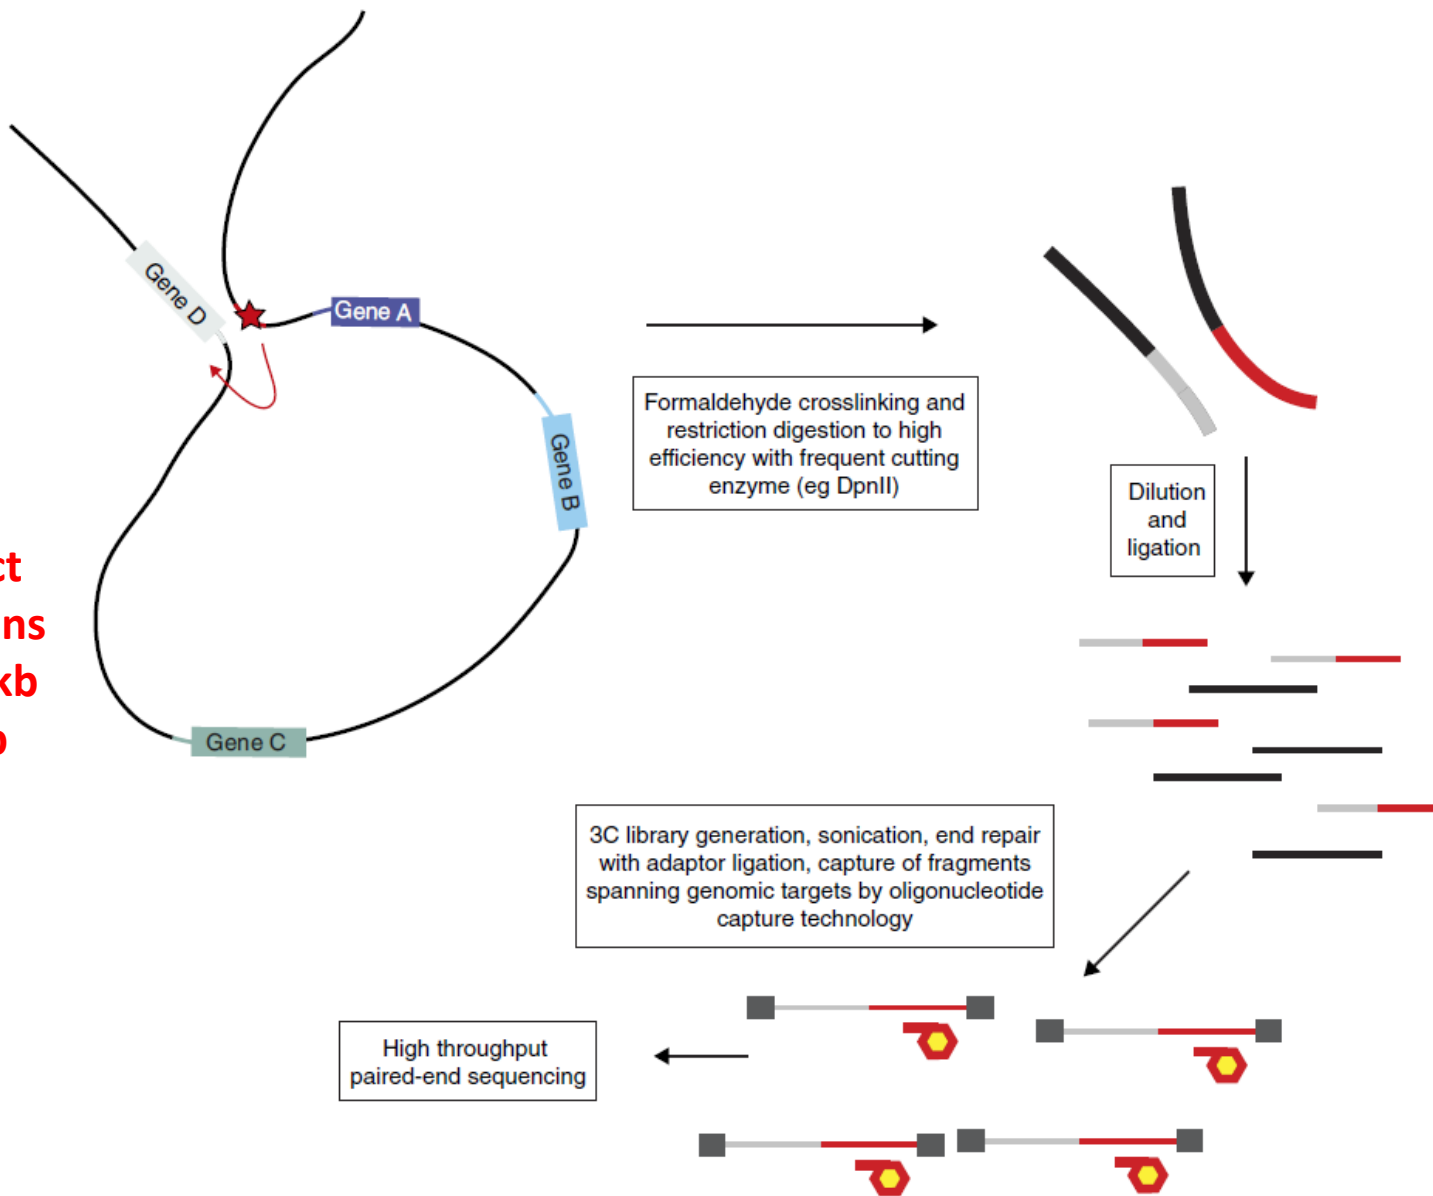

The same variant can modulate expression of **gene D** at a distance through DNA looping that brings the regulatory enhancer element close to the promoter of gene D on the same chromosome.

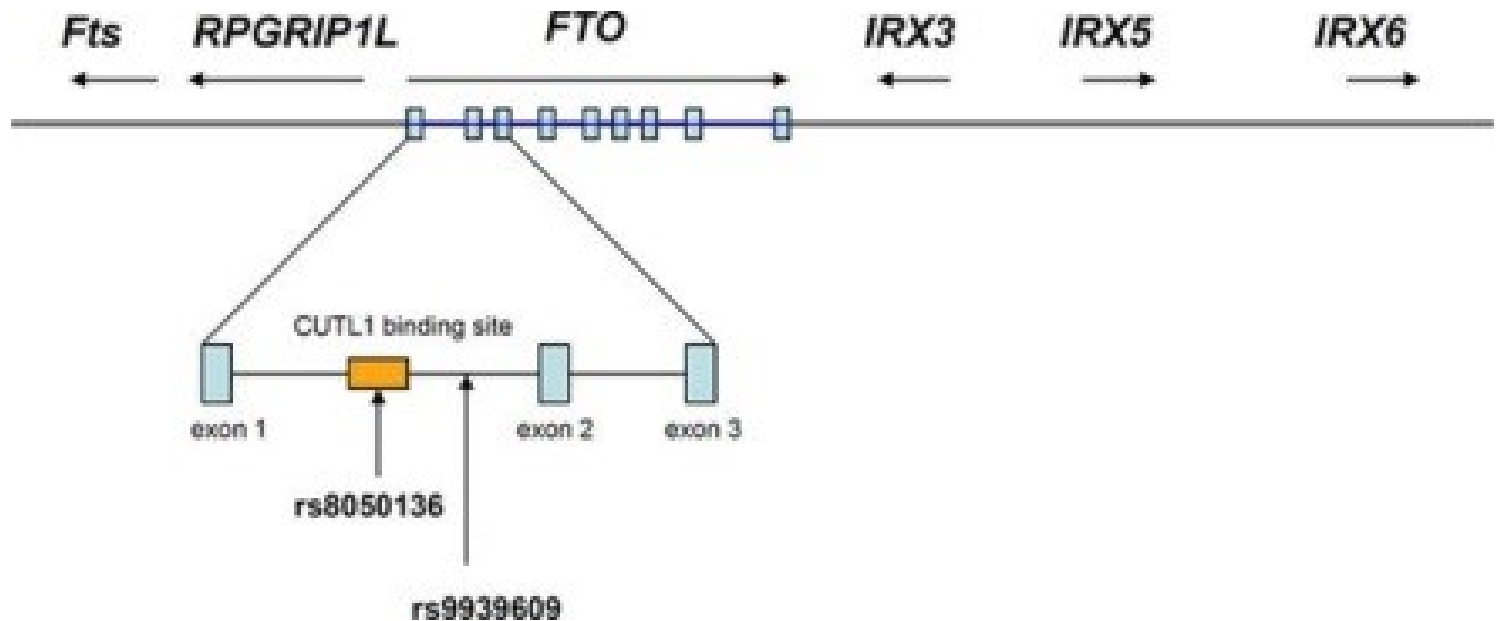

# Chromatin conformation capture (3C) to find the target of a disease-associated SNP within an enhancer element

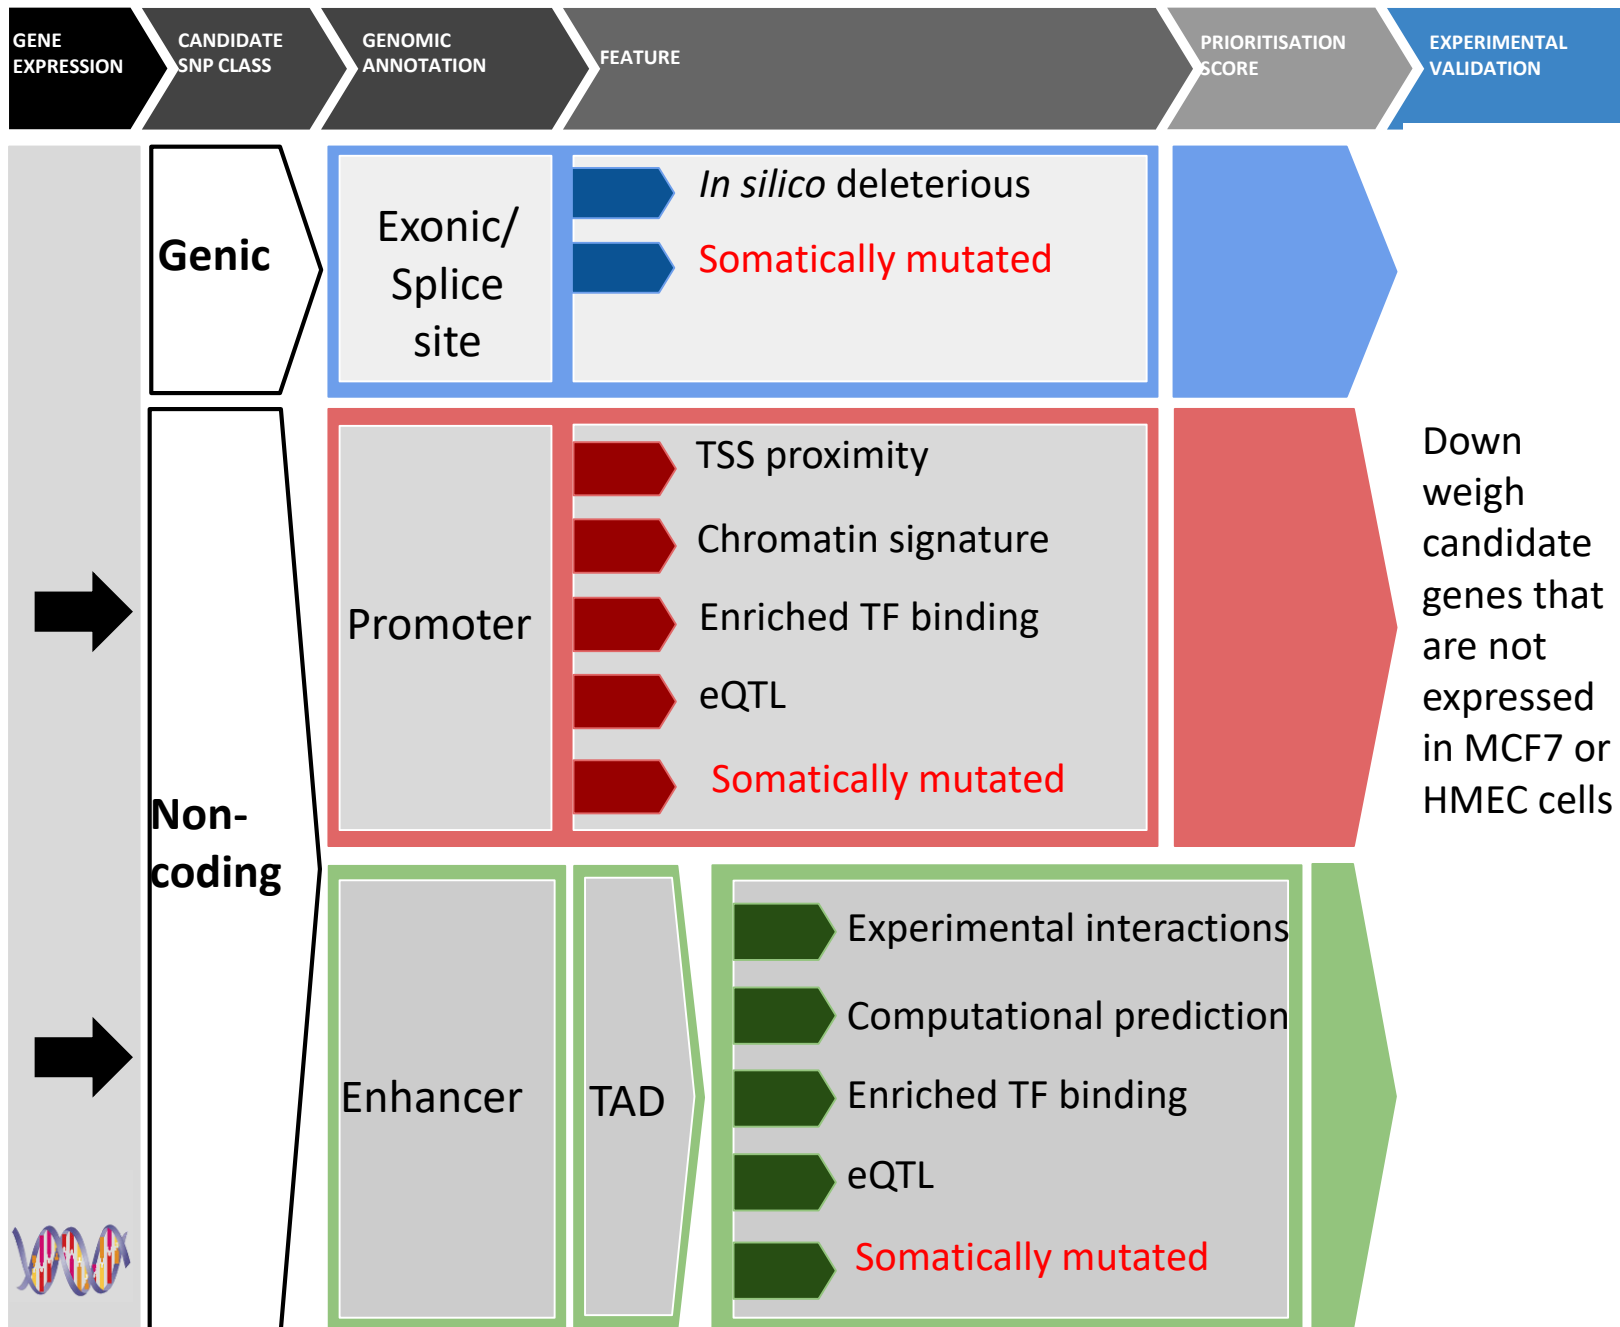

Can detect interactions from ~20kb to ~800kb

Obesity-associated variants within *FTO* form long-range functional connections with *IRX3*  
*Smemo et al 2014*

## GWAS of imputed genotypes

- Increased power
- Better resolution
- Facilitates meta-analysis

# Reference Panels

Our server offers imputation from the following reference panels:

## TOPMed (TOPMed Freeze5 on GRCh38, in preparation)

The TOPmed panel consists of currently 125,568 haplotypes.

Number of Samples	62784
Sites (chr1-22)	463,000,000
Chromosomes	1-22, X
Website:	<a href="https://www.nhlbiwgs.org/">https://www.nhlbiwgs.org/</a>

## HRC (Version r1.1 2016)

The HRC panel consists of 64,940 haplotypes of predominantly European ancestry.

Number of Samples	
Sites (chr1-22)	39,635,008
Chromosomes	1-22, X
Website:	<a href="http://www.haplotype-reference-consortium.org">http://www.haplotype-reference-consortium.org</a> ; HRC r1.1 Release Note

---

# Ways to increase power

Increase sample size

# Larger samples lead to more SNP discovery

*Results of GWA meta-analysis of seven cohorts for MDD. (a) Relation between adding cohorts and number of genome-wide significant genomic regions. Beginning with the largest cohort (1), added the next largest cohort (2) until all cohorts were included (7). The number next to each point shows the total effective sample size.*

# Depression : 135K MDD Cases and 345K Controls

Genome-wide association analyses identify 44 risk variants and refine the genetic architecture of major depression

44 hits

# Polygenic Risk Scores

Polygenic Risk Scores capture (part of) someone's genetic "risk" by summing all risk alleles weighted by the effect sizes estimated in a Genome-Wide Association Study (GWAS)

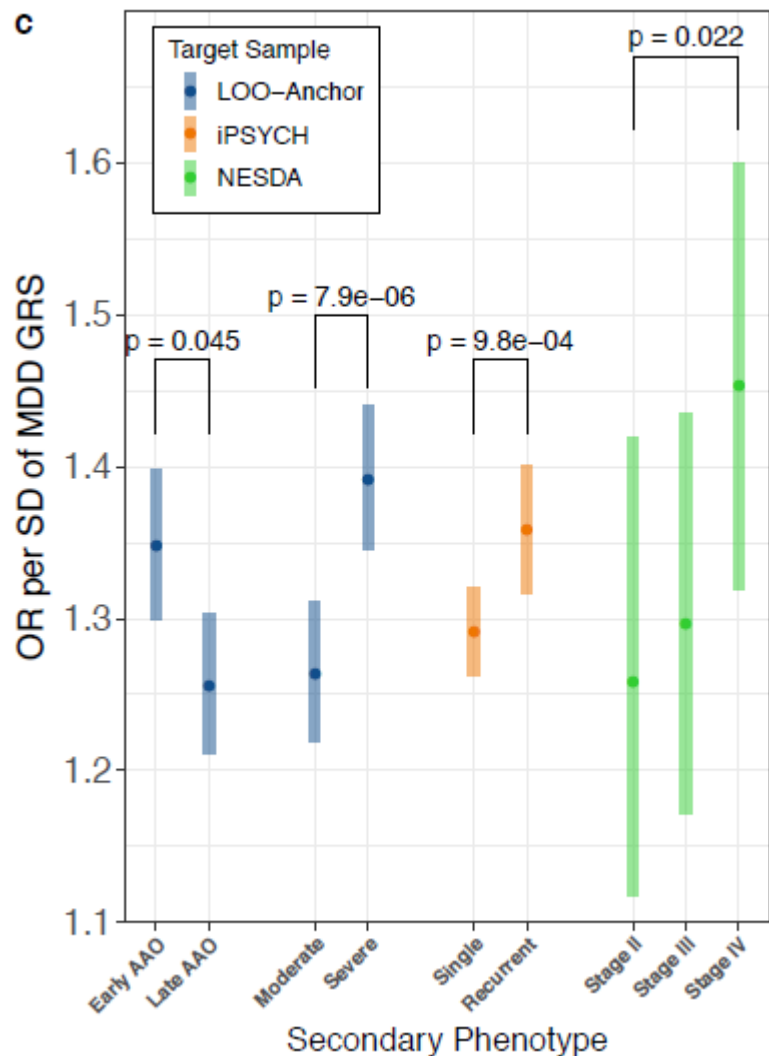

# MDD Polygenic Risk Score predicts risk in independent samples

*Odd ratios of MDD per PRS decile relative to the first decile for iPSYCH and anchor cohorts.*

**Interdecile risk ~2.5**

## MDD Polygenic Risk Score predicts age at onset, recurrence, and severity in independent samples

*MDD PRS (from out-of-sample discovery sets) were significantly higher in MDD cases with:*

- earlier age at onset; more severe MDD symptoms (based on number of criteria endorsed)*
- recurrent MDD compared to single episode*
- chronic/unremitting MDD (“Stage IV” compared to “Stage II”, first-episode MDD)*

*Error bars represent 95% CI*

# GWAS Power

# Gene discovery and polygenic prediction from a genome-wide association study of educational attainment in 1.1 million individuals

James J. Lee<sup>1,58</sup>, Robbee Wedow<sup>2,3,4,58</sup>, Aysu Okbay<sup>5,6,58\*</sup>, Edward Kong<sup>7</sup>, Omeed Maghziian<sup>7</sup>,

- **1,271 independent GWS SNPs**
- **implicate genes involved in brain-development processes and neuron-to-neuron communication**
- **polygenic scores explain 11–13% of the variance in educational attainment and 7–10% of the variance in cognitive performance.**

# GWAS of 126,559 Individuals Identifies Genetic Variants Associated with Educational Attainment

All authors with their affiliations appear at the end of this paper.

A genome-wide association study (GWAS) of educational attainment was conducted in a discovery sample of 101,069 individuals and a replication sample of 25,490. Three independent single-nucleotide polymorphisms (SNPs) are genome-wide significant (rs9320913, rs11584700, rs4851266), and all three replicate. Estimated effects sizes are small (coefficient of determination  $R^2 \approx 0.02\%$ ), approximately 1 month of schooling per allele. A linear polygenic score from all measured SNPs accounts for  $\approx 2\%$  of the variance in both educational attainment and cognitive function. Genes in the region of the loci have previously been

# The value of DZ twins for within-pair association tests for ruling out population stratification

Within-family regression results of the polygenic scores on *College* and *EduYears* in the QIMR and Swedish Twin Registry cohorts using SNPs selected from the meta-analysis excluding the QIMR and STR cohorts.

## Prediction in QIMR + STR

Phenotype (PGS)		$p_{\text{SNPs}} < 5 \times 10^{-8}$	$p_{\text{SNPs}} < 5 \times 10^{-5}$	$p_{\text{SNPs}} < 5 \times 10^{-3}$	All SNPs
<i>EduYears</i> ( <i>College</i> )	$R^2$	0.017	0.003	0.220	0.310
	(%)				
	$P$	0.455	0.739	0.006	0.001
<i>EduYears</i> ( <i>EduYears</i> )	$R^2$	0.002	0.001	0.110	0.190
	(%)				
	$P$	0.791	0.846	0.065	0.011

Analyses for QIMR are based on 572 full-sib pairs from independent 572 families. Analyses for STR are based on 2,774 DZ twins from 2,774 independent families.

# Applications of GWAS

- Investigate genetic correlation
- The genetics of nurture
- Direction of causation

# GWAS meta-analysis of anorexia nervosa (16,991 cases and 56,059 controls)

# Significant genetic correlations (SNP-R<sub>g</sub>) and 95% confidence intervals (error bars) between anorexia nervosa and traits, as estimated by LD score regression

# The nature of nurture: Effects of parental genotypes

Augustine Kong .....Kari Stefansson

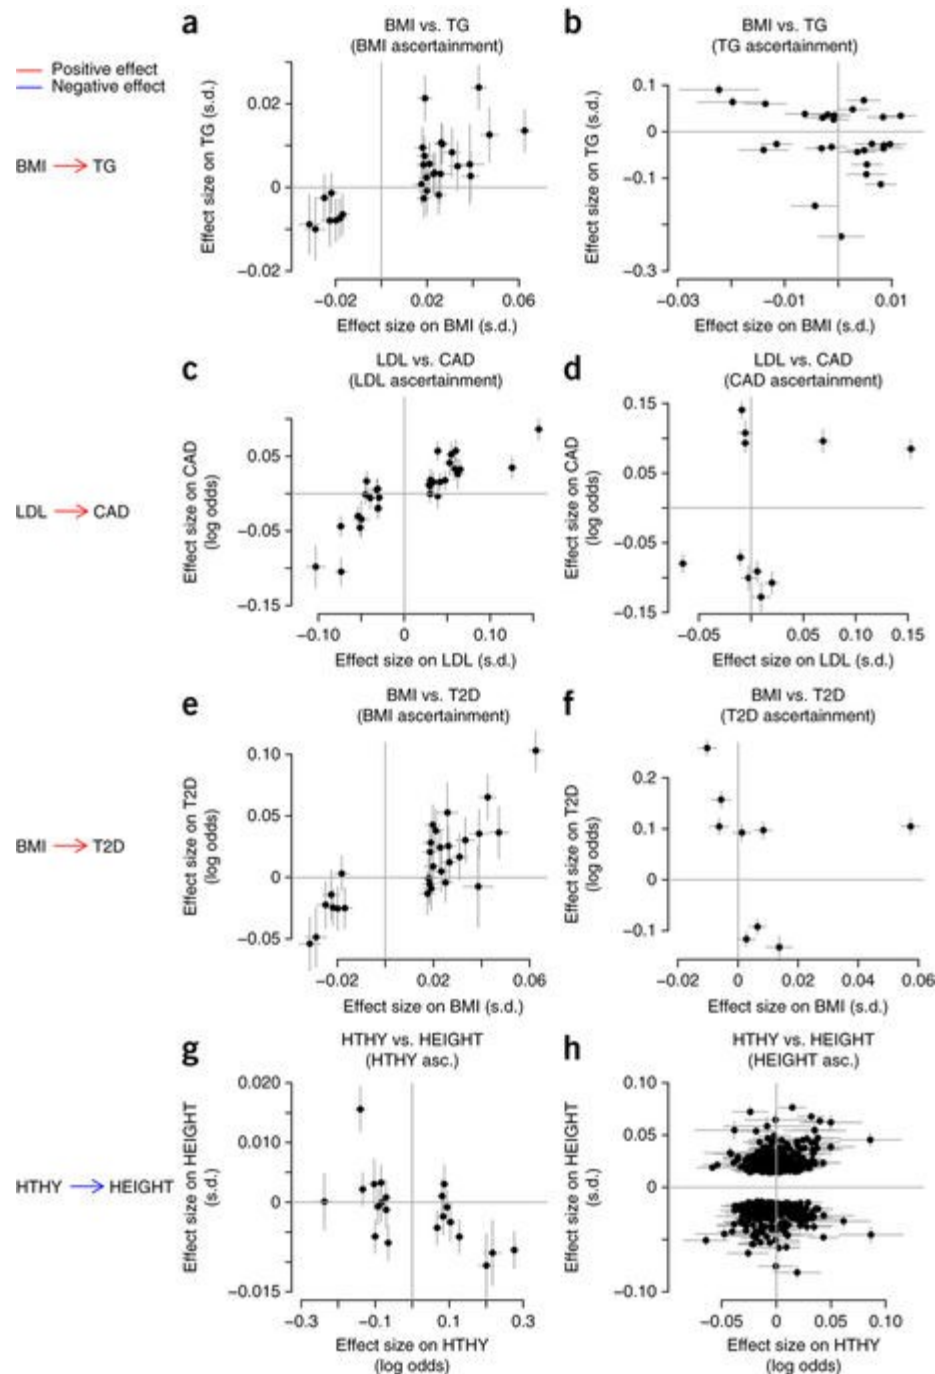

Nontransmitted alleles can affect a child through their impacts on the parents and other relatives, a phenomenon we call “genetic nurture.” Using results from a meta-analysis of educational attainment, we find that the polygenic score computed for the nontransmitted alleles of 21,637 probands with at least one parent genotyped has an estimated effect on the educational attainment of the proband that is 29.9% ( $P = 1.6 \times 10^{-14}$ ) of that of the transmitted polygenic score.

Search for rare variants

# Rare and low-frequency coding variants alter human adult height

A full list of authors and affiliations appears in the online version of the paper.

Height is a highly heritable, classic polygenic trait with approximately 700 common associated variants identified through genome-wide association studies so far. Here, we report 83 height-associated coding variants with lower minor-allele frequencies (in the range of 0.1–4.8%) and effects of up to 2 centimetres per allele (such as those in *IHH*, *STC2*, *AR* and *CRISPLD2*), greater than ten times the average effect of common variants. In functional follow-up studies, rare height-increasing alleles of *STC2* (giving an increase of 1–2 centimetres per allele) compromised proteolytic inhibition of PAPP-A and increased cleavage of IGFBP-4 *in vitro*, resulting in higher bioavailability of insulin-like growth factors. These 83 height-associated variants overlap genes that are mutated in monogenic growth disorders and highlight new biological candidates (such as *ADAMTS3*, *IL1IRA* and *NOX4*) and pathways (such as proteoglycan and glycosaminoglycan synthesis) involved in growth. Our results demonstrate that sufficiently large sample sizes can uncover rare and low-frequency variants of moderate-to-large effect associated with polygenic human phenotypes, and that these variants implicate relevant genes and pathways.

- used an ExomeChip<sup>11</sup> to test the association between 241,453 variants (of which 83% are coding variants with a MAF  $\leq$  5%) and adult height variation in **711,428** individuals (discovery and validation sample sizes were 458,927 and 252,501, respectively)
- The ExomeChip is a genotyping array designed to query in very large sample sizes coding variants identified by whole-exome DNA sequencing of approximately 12,000 participants

**Figure 1 | Variants with a larger effect size on height variation tend to be rarer.** An inverse relationship between the effect size (from the combined

# Schizophrenia genetics complements its mechanistic understanding

Elizabeth K Ruzzo & Daniel H Geschwind

Schematic of the findings and model of Sekar *et al.*<sup>4</sup>. Careful refinement of the schizophrenia GWAS locus in the MHC revealed that structural alleles of the C4 locus increase schizophrenia risk. These structural alleles increase *C4A* RNA levels in human brain, which predict a subsequent increase in C3, increasing synaptic pruning. A mouse knockout of C4 demonstrated that C3 levels decreased and synaptic pruning in the visual system was disrupted, which may be consistent with the model whereby an increase in human *C4A* expression results in increased synaptic pruning in schizophrenia. Points of potential convergence of other influences that may increase risk for this complex condition, such as environment and other genetic influences, are also indicated.

# Polygenic Risk Scores for Prediction of Breast Cancer and Breast Cancer Subtypes

Nasim Mavaddat,<sup>1,\*</sup> Kyriaki Michailidou,<sup>1,2</sup> Joe Dennis,<sup>1</sup> Michael Lush,<sup>1</sup> Laura Fachal,<sup>3</sup> Andrew Lee,<sup>1</sup>

Compared with women in the middle quintile, those in the highest 1% of risk had 4.37- and 2.78-fold risks, and those in the lowest 1% of risk had 0.16- and 0.27-fold risks, of developing ER-positive and ER-negative disease, respectively. This PRS is a powerful and reliable predictor of breast cancer risk that may improve breast cancer prevention programs.

# The support of human genetic evidence for approved drug indications
