score (GWS)

A literal history of polygenic indices

- Once upon a time, people thought all human traits were influenced by a handful of genes.
- In their folly, they came up with candidate genes chosen out of a few whose function were known
Thus, started the era of candidate gene studies, and the following replication crisis.
- In the silence that followed the wake of these studies, tiny little GWAS started to emerge from the ashes
- They identified a few tiny genetic breadcrumbs that barely explained a fraction of the traits they were chasing. The top hits were underwhelming, the heritability gaps yawning...

It was then (2009) that a statistical alchemist came to the rescue.. Today, we know him as...

What is a polygenic index?

Effect size of -1 per T allele

What is a polygenic index?

- An index that linearly aggregates the estimated effects of individual SNPs on the trait of interest.
- Can be considered a measure of an individual's **genetic propensity** towards a trait.
- Defined as a **weighted sum of a persons genotypes at K loci**.
- Start with additive model using measured SNPs:

$$y_i = \underbrace{A_{SNP,i}(x_i)}_{\text{additive SNP factor}} + \epsilon_{i,SNP} = \sum_{j=1}^K \beta_j x_{ij} + \epsilon_{i,SNP}$$

What is a polygenic index?

Additive SNP factor:

$$A_{SNP,i}(x_i) \equiv \sum_{j=1}^K \beta_j x_{ij}$$

True effect size of
SNP j

PGI:

$$\hat{A}_{SNP,i}(x_i) \equiv \sum_{j=1}^K \hat{\beta}_j x_{ij}$$

Estimated effect size of
SNP j

$$\hat{\beta}_j = \beta_j + u_j \Rightarrow \hat{A}_{SNP,i} = \sum_{j=1}^K (\beta_j + u_j) x_{ij} = A_{SNP,i} + U_i \text{ where } U_i = \sum_{j=1}^K u_j x_{ij}$$

If u is mean-zero estimation
error uncorrelated with β_j

U is mean-zero
measurement error

$$E(\hat{A}_i | A_i) = A_i$$

Outline

Predictive power of a polygenic index

If we regress y on \hat{A}_{SNP} we get an OLS coefficient of

$$\begin{aligned}
 b &= \frac{Cov(\hat{A}_{SNP}, y)}{Var(\hat{A}_{SNP})} \\
 &= \frac{Cov(A_{SNP} + U_i, A_{SNP} + \epsilon_{SNP})}{Var(A_{SNP} + U)} \\
 &= \frac{Var(A_{SNP})}{Var(A_{SNP}) + Var(U)}
 \end{aligned}$$

And the expected predictive power is:

$$\begin{aligned}
 R^2 &\approx \frac{b^2 Var(\hat{A}_{SNP})}{Var(y)} \\
 &= \left(\frac{Var(A_{SNP})}{Var(A_{SNP}) + Var(U)} \right)^2 \frac{Var(\hat{A}_{SNP})}{Var(y)}
 \end{aligned}$$

\vdots

$$\approx \frac{h_{SNP}^2}{h_{SNP}^2 + \frac{M_e}{N}}$$

Sometimes called the Daetwyler formula (Daetwyler et al. 2008)

Effective number of SNPs in the PGI, estimated to be between 50k-70k in genome-wide data for EUR ancestry (Wray et al. 2013)

OLS:

$$y_i = a + bx_i + \epsilon_i$$

$$b = \frac{Cov(x, y)}{Var(x)}, R^2 = \frac{b^2 Var(x)}{Var(y)}$$

Theoretical projections for R_{PGI}^2

Predictive power and heterogeneity

What if there is heterogeneity between GWAS and validation samples?

$$A_{SNP,i}^* \neq A_{SNP,i} \rightarrow h_{SNP}^{2*} \neq h_{SNP}^2$$

Define the genetic correlation to be

$$r_g = \text{Corr}(A_{SNP,i}^*, A_{SNP,i})$$

The expected predictive power

$$R^2 \approx \frac{h_{SNP}^2}{h_{SNP}^2 + \frac{M_e}{N}}$$

now becomes

$$R^2 \approx \frac{r_g h_{SNP}^2 h_{SNP}^{2*}}{h_{SNP}^2 + M_e/N}$$

(De Vlaming et al. 2016)

Measuring observed predictive power

Most commonly used measure for continuous phenotypes is **incremental- R^2**

- Regress phenotype on basic covariates (e.g. *sex*, *age*, *age*², *sex* × *age*, *sex* × *age*²) and PCs
- Obtain the R^2 of the regression
- Add the PGI to the RHS, obtain the new R^2
- The difference between the two R^2 's is the incremental- R^2 of the PGI

For binary phenotypes analyzed using logistic regression, various other measures are used, such as

- **Nagelkerke's pseudo- R^2** : $R^2 = \frac{\left(1 - \left\{\frac{L_0}{L_1}\right\}^{\frac{2}{n}}\right)}{1 - L_0^{\frac{2}{n}}}$ where L_0 and L_1 are the likelihoods of the null model (with only covariates) and of the model with PGI, respectively
- **Area under the ROC curve (AUC)**: The probability that the model, if given a randomly chosen positive and negative example, will rank the positive higher than the negative. Ranges between 0.5 and 1.

Constructing polygenic indices

What is needed?

- Individual-level genotype data from a prediction sample.
- Weights: GWAS summary statistics from a discovery sample
- Reference genotypes to estimate LD

Caution: The prediction sample should not overlap with the discovery sample!

Weights

GWAS results give us $\hat{\beta}_j^{GWAS}$, not β_j . Two issues to consider when constructing $\sum_{j=1}^K \hat{\beta}_j^{GWAS} x_{ij}$:

1. For some SNPs, $\hat{\beta}_j^{GWAS}$ may be a very noisy estimate of β_j and/or β_j may be close to 0, so adding those SNPs will add more noise than signal
2. If we include all SNPs, we will overweight (“double-count”) SNPs with high LD scores

Two solutions

Clumping and thresholding

Include only the most strongly associated SNP from each LD block (Purcell et al., 2009)

Weights: Set equal to GWAS coefficients.

Loci: Selected by

1. using a **clumping** algorithm that ensures the included markers are all approximately independent of each other
2. omitting SNPs whose P value for association with the phenotype is above a certain **threshold**

$$\sum_{j=1}^K \hat{\beta}_j^{GWAS} x_{ij}$$

Bayesian approaches

Include all SNPs but adjust the effect sizes for LD

Weights: Set to GWAS coefficients **adjusted for LD** → approximate results from a theoretical multiple regression of the phenotype on all SNPs

Loci: Include **all SNPs**, no LD-based pruning

Examples: LDpred (Vilhjalmsson et al. 2015, Prive et al. 2020), PRS-CS (Ge et al. 2019), SBayesR (Lloyd-Jones et al. 2019)

Predictive power of C+T PGS with different clumping r^2 and P -value thresholds

- **Cohort:** Health and Retirement Study
- **Phenotype:** Educational attainment

Bayesian approaches

Uses as weights

$$E(\beta_j | \hat{\beta}_j^{GWAS}, D) \quad \text{LD matrix}$$

By Bayes's rule,

$$f(\beta_j | \hat{\beta}_j^{GWAS}, D) = \frac{f(\hat{\beta}_j^{GWAS} | \beta, D) f(\beta_j | D)}{f(\hat{\beta}_j^{GWAS} | D)}$$

Shrinkage depends on the prior!

LDpred2: Gaussian or Spike-and-Slab

$$(\beta_j | D) \sim \begin{cases} N(0, \tau^2), & \text{with probability } \pi \\ 0 & \text{with probability } 1 - \pi \end{cases}$$

π can be estimated from data, sparsity allowed
(if $\bar{\pi}_j < \pi$, b_j set to 0), $\tau^2 = h^2 / M\pi$

SBayesR: flexible finite mixture of normal distributions, sparsity allowed

$$(\beta_j | D) \sim \begin{cases} 0, & \text{with probability } \pi_1 \\ N(0, \gamma_2 \sigma_b^2), & \text{with probability } \pi_2 \\ \dots & \\ N(0, \gamma_c \sigma_b^2) & \text{with probability } 1 - \sum_{c=1}^{C-1} \pi_c \end{cases}$$

PRS-CS: "Continuous shrinkage"

$$(\beta_j | D) \sim N(0, \phi \psi_j)$$

$$\psi_j \sim N(a, \delta_j)$$

$$\delta_j \sim N(b, 1)$$

Parameters a and b determine how aggressively to shrink small estimates and how much you don't shrink large ones

Practical considerations – LD reference data

How to choose LD reference data?

- Some software tools (e.g. SBayesR, PRS-CS) make available previously calculated LD estimates
- These are usually limited to a set of good quality SNPs (e.g. HapMap3) to reduce errors in LD estimation and computational burden while ensuring sufficient coverage
- But you can also estimate your own! Why would you?
 - You may want to include more SNPs
 - The available LD reference data may not be a good match for the ancestry of your GWAS
- If you decide to obtain your own LD estimates, you should make sure that the quality of your data is good. Bayesian approaches are very sensitive to errors in LD estimates!

Practical considerations – LD reference data

Points to consider when estimating LD

- The sample is large and **representative of the GWAS sample**
- **Sequenced genotypes are best.** Imputation inaccuracy introduces noise into LD estimates. If you're using imputed data, apply a strict imputation accuracy filter
- Data are cleaned
 - sample-level filters: related individuals, ancestry outliers, individuals with low genotyping rate
 - SNP-level filters: low SNP call rate, MAF, HWE P-value (genotyped SNPs), imputation accuracy (imputed SNPs)
- There are no genotyping or imputation batch effects.
 - May lead to errors in LD estimation if genotyping is done with multiple arrays or imputation in multiple batches.

Practical considerations - GWAS

Restricting set of SNPs

- The SNPs included in the PGI will be limited to the intersection of GWAS, LD reference sample and validation data.
- It is a good idea to **limit the SNPs in the GWAS to those available in the validation data prior to adjusting for LD**, especially if the overlap is rather poor (e.g. if you only have array SNPs in the validation data)
- The Bayesian software will assume all SNPs in the GWAS will be included in the PGI and make LD adjustments to maximize prediction accuracy. If some SNPs cannot be included because they are not in the validation data, the adjustments will be suboptimal.
- As an additional QC step, you can exclude SNPs whose MAF is very different from the LD reference data

Practical considerations – Validation data

- Applying some QC to validation data to minimize noise and genotyping errors is recommended:
 - sample-level filters: limit to a single genetic ancestry, drop individuals with low genotyping rate
 - SNP-level filters: drop SNPs with low call rate, MAF, HWE P-value (genotyped SNPs), imputation accuracy (imputed SNPs)
- Restrict the GWAS to SNPs available in the validation data after the above QC steps are applied
- If you are using imputed data, **use dosages rather than hard calls**. Hard calls don't account for imputation uncertainty!

C+T vs Bayesian approaches

Clumping and thresholding

Faster and easier, but too black & white

- If clumping r^2 or P -value cutoffs too strict, it drops potentially causal SNPs.
- If clumping r^2 and P -value cutoffs too relaxed, there is a lot of double-counting and noise

Bayesian approaches

- utilize information from all SNPs by adjusting SNP weights for LD, but
 - if the reference panel is not a good match for the population from which summary statistics were obtained, prediction accuracy might be compromised
 - the assumed prior distribution might not accurately model the true genetic architecture

If the purpose is to maximize predictive power, then Bayesian approaches clearly do better

Source: Privé, Arbel, Vilhjálmsson (2020)

Source: Lloyd-Jones et al (2019)

There may still be uses for C+T, for example when you want to include SNPs most likely to be associated (e.g. in mendelian randomization)

Outline

- A literal history of PGIs
- What is a polygenic index?
- Predictive power of polygenic indices
- Constructing polygenic indices
- Applications
- Limitations and pitfalls

Applications

Major advantage of PGI over specific genetic variants: can have much greater predictive power

e.g., if $R^2_{PGI} = 0.07$, then 80% to detect its effect in a sample of size ~ 110 individuals. If $R^2_{PGI} = 0.09$, then ~ 85 individuals.

→ Can study PGI in datasets containing high quality measures of outcomes, mediators, and covariates.

Identify correlates of genetic factors

e.g. Educational attainment PGI predicts early speech acquisition and is mediated by cognitive ability (Belsky et al., 2016).

Identify causal effects of genetic factors

Sibling data and family fixed effects → causal effect of PGI

Study GxE

e.g. Increase of compulsory schooling age in U.K. reduces BMI only among those with a high-BMI PGI (Barcellos, Carvalho, and Turley 2016)

Use as control variable

To control for confounding genetic factors or to increase statistical power for estimating the effect of a randomized treatment. If incremental R^2_{PGI} is 15%, then power increase is equivalent to 17% increase in sample size (Rietveld, 2013)

Identify at-risk individuals

Personalized treatment

⋮

Individual-level prediction is not accurate enough for most complex phenotypes!

Source: Okbay et al. (2022)

Prediction with related samples

If you are interested in incremental- R^2 , no need to do anything special, R^2 is still valid, but

- the standard error for the coefficient of the PGI is going to be wrong!

What to do?

- If you have family IDs, cluster standard errors at the family level
- Otherwise, can control for the relatedness using the GRM and a linear mixed model
- Possible to do in GCTA

Outline

- A literal history of PGIs
- What is a polygenic index?
- Predictive power of polygenic indices
- Constructing polygenic indices
- Applications
- Limitations and pitfalls

LIMITATIONS & PITFALLS

Mechanisms are poorly understood.

- Including many genetic variants
 - increases predictive power
 - requires including genetic variants with unknown function
- makes it hard to specify what is captured by PGI.

LIMITATIONS & PITFALLS

The predictive power of the PGI may not be solely due to the causal effect of genetic variants included in the PGI!

- Gene-environment correlation
 - Population stratification
 - Indirect genetic effects
- Assortative mating

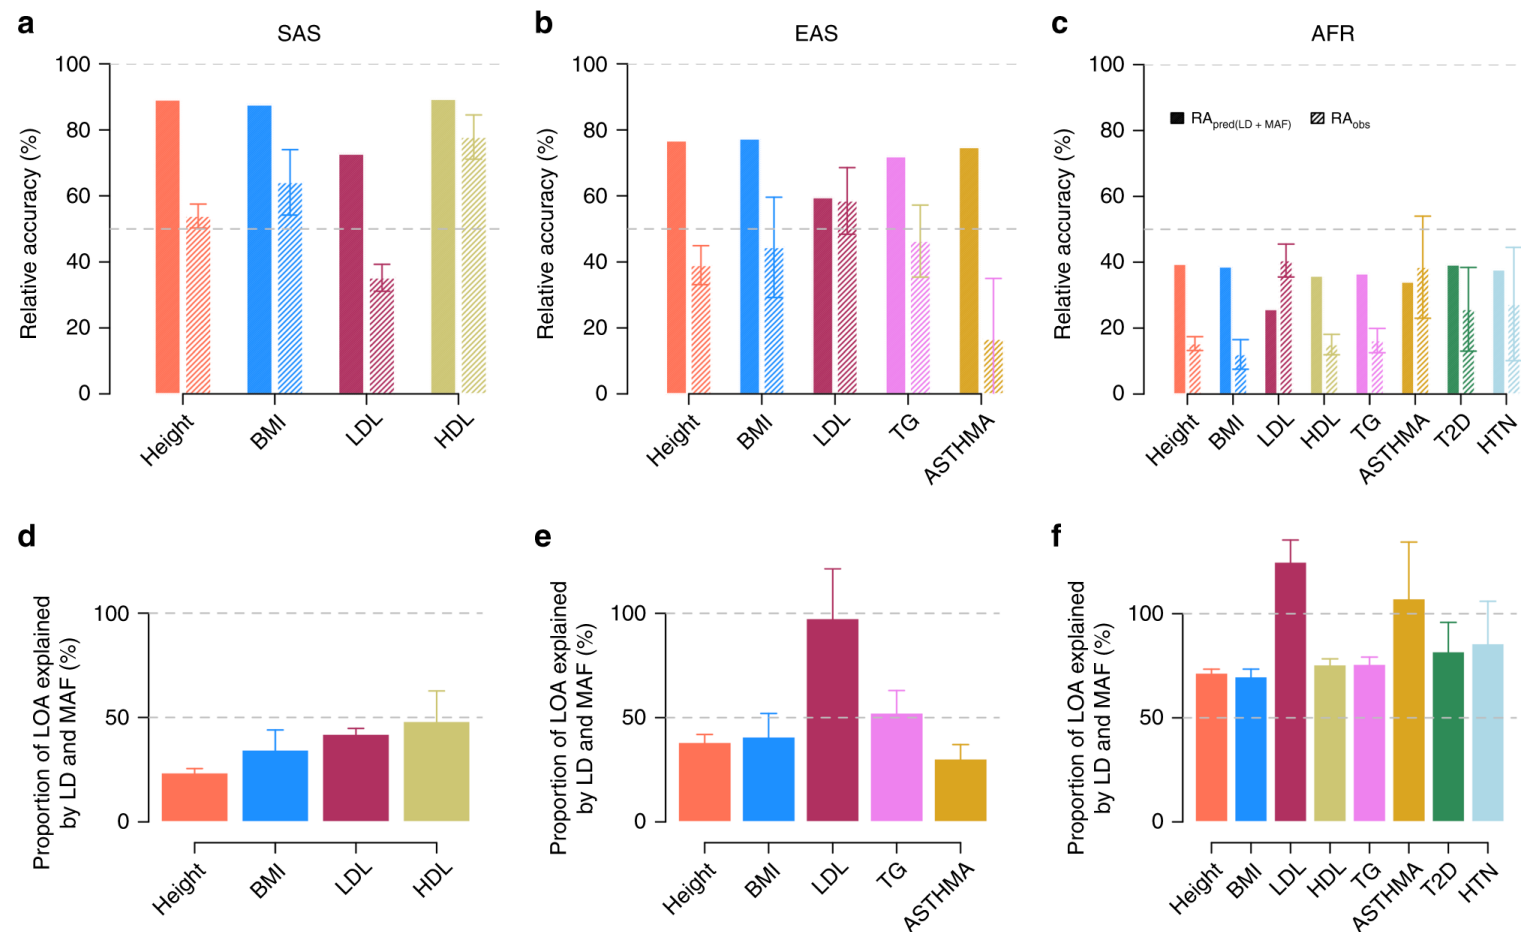

Solutions:

- Within-family prediction
- PGIs based on within-family GWAS

LIMITATIONS & PITFALLS

- Current polygenic indices far less predictive in non-European-descent samples.
- For example, for the EA4 PGI:
 - $R^2 \approx 17\%$ for European-ancestry individuals in Add Health, 13% in HRS.
 - $R^2 \approx 2.3\%$ for African-ancestry individuals in Add Health, 1.3% in HRS.
- Methodologies are being developed to improve cross-ancestry predictive power (e.g. PRS-CSx)
- PGIs incorporating functional annotation (Mega-PRS, SBayesRC) do better

Source: Wang *et al.* (2020)

MEASUREMENT ERROR

A regression equation is shown with color-coded components and arrows indicating their roles:

$$\text{phenotype} \leftarrow y_i = \hat{A}_{SNP,i} \beta + z_i \zeta + w_i \delta + \epsilon_i$$

- y_i is circled in red, with a red arrow pointing to the word "phenotype".
- $\hat{A}_{SNP,i}$ is circled in blue, with a blue arrow pointing to the text "Standardized PGI".
- z_i is circled in green, with a green arrow pointing to the text "Controls".
- w_i is circled in purple, with a purple arrow pointing to the text "Interaction terms".

$\hat{\beta}$ is the expected increase in y corresponding to 1 SD increase in the PGI. Two issues with this:

1. $\hat{\beta}$ will be attenuated due to classical measurement error
2. The SD of the PGI depends on the amount of measurement error in it – how to compare results from different studies using differently constructed PGIs?

Solution: Scale everything to resemble a regression using A_{SNP} instead of \hat{A}_{SNP}

- Very straightforward in a simple regression with only the PGI (scale by $\sqrt{\frac{h^2}{R^2}}$ where R^2 is the predictive power of the PGI) but not so interesting.
- More interesting but a little more complicated when there are controls or interactions correlated with PGI

Papageorge, N. W. & Thom, K. Genes, Education, and Labor Market Outcomes: Evidence from the Health and Retirement Study. *J. Eur. Econ. Assoc.* **18**, 1351–1399 (2020).

Panel A. Association Between EA and the PGI, Without and With Controls for Parental EA

| | Original | | Corrected | |
|-------------|------------------|------------------|------------------|------------------|
| | (1) | (2) | (3) | (4) |
| EA PGI | 0.844 (0.026) | 0.619 (0.024) | 1.318 (0.041) | 1.104 (0.042) |
| Father's EA | - | 0.154 (0.010) | - | 0.112 (0.010) |
| Mother's EA | - | 0.176 (0.011) | - | 0.141 (0.012) |
| # Obs. | 8,537 | 8,537 | 8,537 | 8,537 |

Diagram illustrating the relationship between the EA PGI coefficient and the correction factor:

- Original EA PGI coefficient (1) is 0.844.
- Original EA PGI coefficient (2) is 0.619.
- Corrected EA PGI coefficient (3) is 1.318.
- Corrected EA PGI coefficient (4) is 1.104.
- Relationships: (1) $\times 0.73 \rightarrow$ (2), (2) $\times 1.56 \rightarrow$ (3), (3) $\times 0.84 \rightarrow$ (4), and (2) $\times 1.78 \rightarrow$ (4).

- For EA in the HRS, $\hat{h}_{SNP}^2 \approx 0.25$ and $\hat{R}^2 \approx 0.10$, according to the rule of thumb, coefficients should be expected to have increased by a factor of 1.58 ($\approx \sqrt{0.25/0.10}$).
 - (2) \rightarrow (4) increase is larger due to the positive correlations between the PGI, the controls, and the dependent variable.
- ➔ The correction deflates estimates of how much covariates mediate the effect of the PGI

Resource | Published: 17 June 2021

PGI Repository

- First release includes 47 phenotypes in 11 datasets.
- PGIs based on GWAS including 23andMe for many phenotypes.
- Second release about to come out
 - 20 datasets
 - 60 phenotypes: anthropometric, cognitive, reproductive, biomarkers, health, psychiatric, substance use
 - Parental PGIs based on imputed parental genotypes in datasets with sib or parent-offspring pairs

Resource profile and user guide of the Polygenic Index Repository

QUESTIONS?

Practical

- Five steps:
 1. GWAS sumstats
 2. Genotype data
 3. SBayesR
 4. Making PGIs
 5. Prediction
- It is ok if you don't finish it all, feel free to work on the remaining parts in your own time.
